classDependency

The purpose of this class is to load all the required dependency. Dependencies are automatically injected according to the mapping in Metadata.EntityRelationships. In this table the parentEntityId is the main entity being processed, the childEntityId is the dependent (base) entity to be loaded in order to help produce the main target entity. In this table there is also a loadType column which determines how the base table data is queried and ultimately provided to the developer for use.

Methods available within the class are as defined below:

Method Name	Description	Arguements	Input	Output
__init__	Python's silent constructor method used to instantiate the class	Should not be called directly	dependency = classDependency(entityId)	No output expected, although now there is an object called dependency we can use to continue processing
load	Automatically loads tables into a temp view with the desired load type method	N/A	dependency.load()	Info: Prepared latest version of awbiJest using temp table awbiJestLatestFull ... Info: Prepared latest version of awbiJsto using temp table awbiJstoLatestFull ...
